SUPERVISOR DECLARATION

“I hereby declare that I have read the report and in my opinion this report is sufficient in terms of the scope and quality for the award of Bachelor Degree of Electronic and Computer Engineering (Wireless Communication) with Honors”.

Signature :
Supervisor name : DR. SITI KHADIJAH BINTI IDRIS
Date :

The project and research work is dedicated to my beloved parents for their devoted caring throughout my life, my beloved sibling and my friends for their encouragement and assistance.

ACKNOWLEDGEMENT

First of all, I am really grateful to Almighty Allah S.W.T because the strength that he gave me, finally I have finished my Project Sarjana Muda II. I am also very grateful to Almighty Allah S.W.T for granting me the wisdom and strength to face and overcome the challenges and obstacle to accomplish this PSM II.

I thank my academic supervisor Dr. Siti Khadijah Binti Idris, for her supervision through the period of my PSM. Her guidance and help for this period helped me to understand better on working this report. It has been truly memorable and educative being student under her supervision.

Last but not least, I would like to express my sincere to my thanks to my friends which involve during my PSM 1 and PSM 2. Their ideas and knowledge have helped me to complete this project.

ABSTRACT

This project proposed the design of SiGe optical modulator with NPN configuration by using Silvaco application. The accurate design is required to develop the best performance of optical modulator device. The designs are developed using instruction in DECKBUILD. The doping type for the design will be changed using 3 different types of material which are Boron, Aluminum and Indium for P⁺ doping while Antimony, Phosphorus and Arsenic for N⁺ doping. The performance of each doping type will be determined using the beam propagation method (BPM). A different performance when varying doping material is expected to be developed. The parameter which has been analyzed is refractive index and absorption loss. From the simulation and analysis, it was observed that doping material using Antimony as N⁺ and Indium as P⁺ give the highest reflection index change compared to other materials. While doping material using Phosphorus as N⁺ and Boron as P⁺ give the lowest absorption loss compared to other materials.

ABSTRAK

Projek ini mencadangkan rekabentuk SiGe pemodulat optik dengan konfigurasi NPN menggunakan aplikasi Silvaco. Rekabentuk pemodulat optik yang tepat diperlukan untuk membina peranti dengan prestasi yang terbaik. Reka bentuk ini adalah dibangunkan dengan menggunakan kod arahan dalam DECKBUILD. Jenis dopan untuk rekabentuk akan diubah menggunakan 3 jenis bahan iaitu Boron, Aluminum dan Indium untuk P+ dopan manakala Antimony, Phosphorus dan Arsenic untuk N+ dopan. Prestasi setiap jenis dopan akan ditentukan menggunakan kaedah penyebaran pancaran (BPM). Prestasi yang berbeza akan diperoleh apabila menggunakan bahan dopan yang berbeza. Parameter yang telah dianalisis adalah indek biasan dan kehilangan penyerapan. Berdasarkan hasil simulasi dan analisa, didapati bahawa Antimony sebagai N+ dopan and Indium sebagai P+ dopan memberi nilai indek biasan tertinggi berbanding bahan lain. Manakala bahan dopan menggunakan Phosphorus sebagai N+ dopan dan Boron sebagai P+ dopan memberi nilai kehilangan penyerapan terendah berbanding bahan lain.

CHAPTER 1

INTRODUCTION

1.1 Introduction

Optical modulator is a device which is used to modulate a beam of light. Optical modulators may be categorized into amplitude modulators, phase modulators or polarization modulators. For all type of modulator, the performance is an important parameter for example the performance of optical modulator is depending on doping material. Therefore, in this project SiGe (Silicon Germanium) optical modulator with NPN configuration is design and the performance using varies doping type is investigate. The scope of this project limited to 3 type of doping material which are Boron, Aluminum and Indium for P+ doping while Antimony, Phosphorus and Arsenic for N+ doping for SiGe optical modulator with NPN configuration. The development of this project is include of designing metal contact, doping material and SiGe layer. The device has an NPN structure where three side doping regions are joined as a common anode or cathode. A different performance when varying doping material is expected to be developed.

1.2 Problem Statement

Optical modulator is a device which is used to modulate a beam of light. Optical modulators itself may be categorized into amplitude modulators, phase modulators or polarization modulators. As other optical device, the performance of modulator is very important in order to improve the signal transmitted. As for optical modulator, the performance is depend on doping material. Each doping material has different doping level to each other. Improving the doping level for N⁺ and P⁺ will increase the speed as well as increasing the performance of device.

1.3 Objective

The objectives of this project are listed below:

- a. To develop SiGe optical modulator with NPN configuration
- b. To analyze the performance of SiGe optical modulator with NPN configuration
- c. To study the effect of doping materials variations on SiGe optical modulator
- d. To determine the best doping material

1.4 Scope of Project

The scope of this project is limited to 3 type of doping material for SiGe optical modulator with NPN configuration. The development of project consists of designing metal contact, doping material and SiGe layer. The device has an NPN structure where three side doping regions are joined as a common anode or cathode. The doping material for P⁺ is Boron, Aluminum and Indium while for N⁺ is Antimony, Phosphorus and Arsenic.

1.4.1 Study & Research

All information related to the project are been search through article, journal or conference papers. The action is taken to develop knowledge and understanding about the project.

1.4.2 Software Design

The development of SiGe optical modulator with NPN configuration is done using Silvaco application. The process involves ATHENA module for structure design and ATLAS module for measurement result.

1.5 Summary of Thesis

Chapter 1 is an introduction of SiGe optical modulator. Chapters 2 explain the literature review of the SiGe optical modulator. Chapter 3 discuss about the methodology of the project. Chapters 4 explain the result of the project. Chapter 5 discuss about conclusion and recommendation of the project.

CHAPTER 2

LITERATURE REVIEW

2.1 Literature Review

This chapter explain the literature review on theoretical and practical concepts applied in this project. It contains all related background study and information gathering in order to complete this project. It give information regarding of process design, Silvaco application and module involve in the project.

2.2 Optical Modulator

Optical interconnects need a light source, a modulator, a passive distribution of the optical signal from one point to several points and integrated photodetectors at each end. Except for the source, which is supposed to be external, physical properties of silicon are not advantageous for the conception of such devices due to the indirect bandgap and to the crystal symmetry. So reaching the target frequency operation is a real challenge that needs advanced optimizations. The effective bandwidth can be strongly limited by RC constants.

The doped regions of the PIN diode and the metallic contacts have to be optimized to reduce the RC (Resistance Capacitance) constants while maintaining low optical losses for the guided wave. At zero bias, free carriers (holes) generated from the doped layers are trapped in the wells. Under reverse bias applied to the PIN diode, holes are extracted from the wells and swept out of the structure, leading to a refractive index variation. The phase of the optical wave getting out of the active region depends on the refractive index.

Therefore the refractive index variation created in this structure by the electrorefractive effect, under a reverse bias polarization, induces a phase modulation of the optical guided wave propagating through the structure.

2.3 Optical Loss

The optical losses cause by carrier absorption can be determined using the beam propagation method (BPM). The total of the hole and electron concentration need to be measured based on NPN structure. The absorption coefficient variations and refractive index can be determine using formula as below, [2] ;

$$\begin{aligned}\Delta n &= \Delta n_e + \Delta n_h \\ &= -[8.8 \times 10^{-22} \cdot \Delta N_e + 8.5 \times 10^{-18} \cdot (\Delta N_h)^{0.8}] \\ \Delta \alpha &= \Delta \alpha_e + \Delta \alpha_h \\ &= 8.5 \times 10^{-18} \cdot \Delta N_e + 6.0 \times 10^{-18} \cdot \Delta N_h\end{aligned}$$

Which

Δn = change in refractive index

Δn_e = change in refractive index cause by change in electron concentration

Δn_h = change in refractive index cause by change in hole concentration

ΔN_e = change in refractive index cause by change in electron concentration at point

ΔN_h = change in refractive index cause by change in hole concentration at point

$\Delta \alpha$ = change in absorption

$\Delta\alpha_e$ = change in absorption cause by ΔN_e

$\Delta\alpha_h$ = change in absorption cause by ΔN_h

The estimate length of optical device can be measure using formula as below:

$$L_\pi = \lambda/2 \Delta n \quad \text{Where } \Delta n \text{ is change in refractive index}$$

The phase shift can be measure using formula as below:

$$\Delta\theta = 2\pi\Delta n L/\lambda \quad \text{Where}$$

Δn is change in refractive index
L is length of optical device
 λ is wavelength

The absorption loss can be measure using formula as below:

$$\alpha_\pi = 10 \log (\exp[- (\Delta\alpha) L_\pi]) \quad \text{Where}$$

$\Delta\alpha$ is change in absorption
 L_π is estimate length of optical device

2.4 Silvaco Module

This project only involves software application or simulation using Silvaco. There are two modules that are used during this project which are ATHENA and ATLAS. ATHENA is one of software application that specifically builds to design the fabrication process of optical modulator. ATHENA has advantage of capability to create impressive simulation analysis which can be implementation as real fabrication as in industry.

ATHENA use a simple framework by joining all design processes such as impurity diffusion and oxidation, topography simulation, and lithography simulation to make sure the application is easy to use hence user friendly. There are several modules that can be categorize under ATHENA which were listing in Table 2.1.

Table 2.1: ATHENA Module Description

Module	Description
ATHENA	Simulate structure initialization and manipulation, and supply basic deposition and etch process
SSUPREM4	Need in order to design, analysis, and optimization of optical modulator structures. Involve in fabrication process which is ion implantation, diffusion and oxidation.
ELITE	Use to provide 2D view simulator that explain some of process such as deposition, etch and reflow that used in Integrated Circuit
OPTOLITH	Simulate based on optical lithography process
FLASH	Need in the design, analysis and optimization of compound semiconductor structures.

ATHENA is designed to be used in conjunction with the VWF INTERACTIVE TOOLS which includes DECKBUILD, TONYPLOT, DEVEDIT, MASKVIEWS, and OPTIMIZER. Table 2.2 shows the ATHENA facility description.

Table 2.2: ATHENA Facility Description

Facility	Description
Bake	Time and temperature bake specification Models photoresist material flow Models photo-active compound diffusion
C-Interpreter	Allows user access to diffusion coefficient calculation Allows user access to activation calculation Allows user access to segregation calculation
Deposition	Conformal deposition model Hemispherical, planetary, and conical metallization models Unidirectional or dual directional deposition models CVD model
