## **ABSTRAK**

Keadaan trafik masa kini semakin buruk dan akan menjadi suatu kesukaran sekiranya ambulans dalam keadaan kecemasan. Situasi trafik termasuk di kawasan lampu isyarat. Lampu isyarat memainkan peranan yang penting dalam pengurusan trafik untuk mengawal lalu lintas di jalan raya. Semasa kesesakan lalu lintas di kawasan lampu isyarat, ia adalah sukar bagi ambulans untuk menyeberangi jalan raya terutamanya di jalan utama yang melibatkan banyak simpang. Oleh itu, "Automatik Pengawal Trafik Light untuk Ambulans" digunakan untuk membantu ambulans melintasi lampu isyarat dalam keadaan kecemasan. Automatik pengawal lampu isyarat untuk ambulans merupakan projek yang menggunakan PIC untuk program keutamaan berasaskan pengawal lampu isyarat untuk ambulans. Semasa situasi kecemasan di persimpangan lampu isyarat ambulans boleh mengaktifkan perubahan lampu isyarat dari merah kepada hijau untuk membuat laluan untuk perjalanan ambulans. Jika lampu isyarat menunjukkan warna hijau, tempoh masa akan ditangguhkan sehingga selesai ambulans melintas jalan. Penghantaran isyarat akan dilakukan dengan menggunakan pautan RF. Operasi lampu isyarat akan kembali kepada normal apabila ambulans selesai melintas jalan. Projek ini telah berjaya direka, dilaksanakan dan dianalisis. Merujuk kepada hasil kajian yang telah dijalankan, ia menunjukkan bahawa jarak maksimum pengesanan untuk projek ini adalah 55 meter dan masa kelewatan akan meningkat apabila jarak antara transmitter dan receiver bertambah.

## **ABSTRACT**

Traffic situation nowadays is getting worse and will be difficult in the event of an ambulance in emergency situation. This traffic situation is including at traffic light area. Traffic light plays such important role in traffic management to control the traffic on the road. During traffic congestion at traffic light area, it is difficult for ambulance to cross the road especially at main road which involves many junctions. Therefore, the “Automatic Traffic Light Controller for Ambulance” is used to help the ambulance crossing the traffic light during emergency situation. Automatic traffic light controller for ambulance using PIC is a project to program priority based traffic light controller for ambulance. During an emergency situation at traffic light junctions the ambulance can trigger the traffic light to change from red to green to make path for its way. If the traffic light shows green, the time duration will be delayed until the ambulance finish crossing the road. Signal transmission will be done using RF link. The traffic light operation will turn back to normal when ambulance finishes crossing the road. This project was successfully designed, implemented and analyze. Refer to the analysis result it state that the maximum range detection for this project is 55 meters and time delay increases when the distances between transmitter and receiver increases.

## **ACKNOWLEDGEMENTS**

I would like to express my greatest gratitude to Madam Norlezhah Binti Hashim from Faculty Technology Engineering, supervisor of this project for her advices, dedication, efforts and tremendous support. Special thanks to my peers for their assistance and support throughout this project. Special thanks to my beloved parents for their moral support. Lastly, thank you to all my teammates who had been to the crucial parts of realization of this project.

## **DEDICATION**

This thesis dedicate to my parents and my friends for supporting me all the way.

# **CHAPTER 1**

## **INTRODUCTION**

This section basically briefs the background of traffic system. It is including the statistic the rapid of vehicles and history of traffic light as a control system. This chapter also state about the objective, problem statement and also the work scope of this project.

### **1.1 Background**

The monitoring and control of vehicular traffic give a hard challenge in many countries. The increasing numbers of vehicles in the cities not only has a huge environmental impact, but also result in loss of time and loss of lives on the road. This situation demands a comprehensive approach involving a system which coordinates the traffic controls for smooth flowing vehicles. According to the Ministry of Transport, Malaysia (MOT), its state that the traffic congestion is not only difficult for passengers, it also resulted huge losses in terms of productivity and will affect the ability of cities to compete globally. To overcome this problem, there is a tendency for cities to build more roads. However, the cost which includes financial, social and environmental responsibility will increase when the urban development level has reached a certain level.

Based on statistic the rapid increase of vehicles can be seen even within the same year. Addition of these vehicles can also contribute to the problem of traffic congestion as state by traffic consultant Goh Bok Yen said, “This is because the traffic problem in Kuala Lumpur has accumulated over the last 20 years. It is only in the last five years that we have given emphasis to the role of public transportation in city development,” (The Star Online, 2013). It show the way some of solution about controlling traffic.

One of the tools that are currently used to control of vehicle traffic is traffic lights. Traffic lights show the right of way to road users when it safe to cross by displaying lights of a standard color following a universal color code for that place (Jianhua, 2009). In Malaysia, there have commonly three of main light, red, yellow, and green. The red signal prohibits any traffic from proceed the crossing or movement, the yellow light denoting prepare to stop at the intersection and the green light allows traffic to proceed in the direction denoted.

The first historical of traffic light came into creature before the automobile was in use, and traffic consisted only of pedestrians, buggies, and wagons. Installed at an crossroads in London in 1868, it was a device had lights and it used arms which extended outwards. It was operated manually by a police officer . The signal was 22 feet high and crowned with a gas light with red and green signals. Red meant "stop" and green meant "caution". The light, illuminated by gas, was turned by means of a lever at its base so that the suitable light faced traffic. On January 2, 1869, this crude traffic light exploded, injuring the policeman who was operating it.

After the coming of automobiles, the situation got even worse. Police Officer William L. Potts of Detroit, Michigan, decided to do something about the problem. What he had in mind was figuring out a way to adapt railroad signals for street use. The railroads were already utilizing automatic controls. But railroad traffic traveled along parallel lines. Street traffic traveled at right angles. Potts used red, amber, and green railroad lights and about thirty-seven dollars worth of wire and electrical controls to make the world's first 4-way three color traffic light (Pollard, 2008). It was installed in 1920 on the corner of Woodward and Michigan Avenues in Detroit.

Within a year, Detroit had installed a total of fifteen of the new automatic lights. At about the same time, Garrett Morgan of Cleveland, Ohio realized the need to control the flow of traffic. A gifted inventor and reportedly the first African American to own an automobile in Cleveland, Ohio, he invented the electric automatic traffic light. Many others had obtained US Patents for Traffic Signals, some as early as 1918. But Morgan's Patent was purchased by General Electric

Corporation and provided the protection they needed to begin building a monopoly on traffic light manufacture.

As computers started to evolve, traffic light control also advanced computers that were better at vehicle detection (McShane, 1999). The computers maintained control over 159 signals in the cities through telephone lines. People praised the computers for their detection abilities. Thanks to detection computers could change the length of the green light based on the volume of waiting cars. The rise of computers is the model of traffic control which is now used in the 21st century.

Figure 1.1: Chronology of traffic light

Due to the rapid increase of vehicles, congestion often occurs. But congestion at the traffic light causes emergency vehicles such as ambulances are not able to pass through the intersection immediately could be avoided if a traffic light has a control system.

Automatic traffic light controller for ambulance using PIC is a project to program priority based traffic light controller for ambulance. During an emergency situation at traffic light junctions, the ambulance can trigger the traffic light to change from red to green to make path for its way. If the traffic light shows green, the time duration will be delayed until the ambulance finishes crossing the road. The signal will be send using RF link. The traffic light operation turns back to normal when ambulance finishes crossing the road.

## **1.2 Objective**

The purpose of the project is to be able to design a system that can trigger the traffic light from red to green when ambulance is in emergency situation. The other purpose is to analyze the system in terms of reception of distances and delay measurement.

## **1.3 Problem Statement**

Traffic situation nowadays is getting worse and will be difficult in the event of an ambulance in emergency situation. This traffic situation is including at traffic light area. Traffic light plays such important role in traffic management to control the traffic on the road. During traffic congestion at traffic light area, it is difficult for ambulance to crossing the road especially at main road which involves many junctions. Therefore, the “Automatic Traffic Light Controller for Ambulance” is used to help the ambulance crossing the traffic light during emergency situation.

## **1.4 Work Scope**

This project used RF link to transmit and receive signal. The traffic light also need to be change to green when ambulance reach near to the traffic signal (approximately 100 meter). This project also used PIC microcontroller 16F877 as a main role of this project. The maximum range for RF detection in this project is around 60 meters.

## **1.5 Conclusion**

In conclusion, this chapter briefly about the background traffic system. It is including the statistic the rapid of vehicles and history of traffic light as a control system. The statistic states the increases population of transportation can contribute to traffic congestion in Malaysia. This chapter also state about the objective that play the main purpose of this project to be able to design a system that can trigger the traffic light from red to green when ambulance is in emergency situation and be able to analyze the system in terms of reception of distances and delay measurement. It is also state that the problem statement and the work scope of this project as a guideline to implement this project.

## **CHAPTER 2**

### **LITERATURE REVIEW**

A lot of studies have been made for this project, Automatic Traffic Light Controller for Ambulance. These studies are mostly from the journals, conference papers and books. This chapter will discuss the current traffic condition, type of traffic light that had been used, the available wireless systems also the one used in this project and the programming language that used involved in this project to design the system that can control and trigger the traffic light at path of ambulance during an emergency situation.

#### **2.1 Traffic Congestion**

Traffic congestion as demand approaches the capacity of a road (or of the intersections along the road), extreme traffic congestion sets in. They occur at highway and event at traffic light junction. When vehicles are fully stopped for periods of time, this is colloquially known as a traffic jam. Traffic congestion occurs when a volume of traffic or modal split generates demand for space greater than the available road capacity. There are a number of specific circumstances which cause or aggravate congestion. Most of them reduce the capacity of a road at a given point or over a certain length, or increase the number of vehicles required for a given volume of people or goods. About half of U.S, traffic congestion is recurring, and is attributed to sheer weight of traffic; most of the rest is attributed to traffic incidents, road work and weather events (US Department of Transportation, 2008).

Figure 2.1: Traffic congestion condition

A market research by Frost and Sullivan on 1,227 respondents in Kuala Lumpur has revealed that 41% of the respondents ranked traffic jam and congestion as their number one frustrations, higher than Asia-Pacific's average of 35% and global average of 29% (Bernama, 2014). Kuala Lumpur is also bound to face challenges of congestion ahead as car ownerships continued to grow.

Traffic research still cannot fully predict under which conditions a "traffic jam" as opposed to heavy, but smoothly flowing traffic may suddenly occur. It has been found that individual incidents such as accidents or even a single car braking heavily in a previously smooth flow may cause ripple effects (a cascading failure) which then spread out and create a sustained traffic jam when, otherwise, normal flow might have continued for some time longer.

Traffic congestion occurs in time, space and some of factor. It is a spatiotemporal process. Therefore, another classification schema of traffic congestion is associated with some common spatiotemporal features of traffic congestion found in measured traffic data. Common spatiotemporal empirical features of traffic congestion are those features, which are qualitatively the same for different highways in different countries measured during years of traffic observations. Common features of traffic congestion are independent on weather, road conditions and road infrastructure, vehicular technology, driver characteristics and also day time.

Traffic congestion give the negative effects to people such as wasting time, fuel, make a delay in user daily business planning which may result in late arrival for employment, meetings, and education, resulting in lost business, disciplinary action or other personal losses. It is also cause of inability to forecast travel time accurately and can bring the stressed and frustrated to driver or passenger. Traffic congestion also gives the problem to user when in emergencies time. Blocked traffic may interfere with the passage of emergency vehicles traveling to their destinations where they are urgently needed.

## **2.2 Type of Traffic Light**

One of the main advantages of traffic light is that it minimizes the conflict points within an intersection by sharing the available time between competing traffic streams. Based on statistic road crashes in Malaysia in 2006 stood that the number of road accidents was 341,232 and this resulted in 6,287 deaths among road users. This numbers are considered high for a population of 26,640,000 giving an index of 23.5 road fatalities per 100,000 inhabitants. One of the possible reasons for the high number of crashes and injuries is due to beating traffic lights. The problem of increased vehicular flow on the road also increases the traffic congestion. There is an urgent need to optimize traffic control to accommodate the increase in vehicles in urban traffic which experience long travel times due to inefficient traffic light control especially to avoid a delay time for ambulance to arrive at the destination during emergency. There are several types of conventional methods of traffic light control:

- (i) Pre-timed traffic light
- (ii) Countdown traffic light
- (iii) Traffic light with sensor

The most common is the pre-timed traffic light with the signal timing cycle length usually falling between 45 and 120 seconds. The timing for each signal is determined based on traffic volume and traffic patterns in each particular area. The second type is a traffic light with a countdown timer. It is a digit time indicator, placed on the pole above the traffic signal. Its purpose is to reduce congestion at traffic junctions, help motorists to have a better understanding of the traffic flow and helps motorists to be aware of the remaining time left on the green phase. Traffic signal systems are designed to maximize the capacity of junctions whilst maintaining an operating environment which is as safe as possible.

Figure 2.2: Traffic light with countdown timer

Another type is traffic light with a sensor. This system maximizes the efficiency at a traffic junction by allocating green time for each approach to a traffic junction according to traffic demand. This means that if the sensor detects that the demand of a particular approach is higher, it will redistribute the green time accordingly to optimize the usage of the traffic junction. Based on this type, it's more help if the traffic light have been control to give the priority for ambulance to cross its path without the occurrence of collision at the traffic light junction.

## **2.3 Wireless Transmission**

The wireless transmission data that will be used is Radio Frequency (RF) to transmit and receive data but there are also have some other wireless technology that can be used such as GSM, Bluetooth and Wi-Fi.

### **2.3.1 Global System for Mobile Communications (GSM)**

GSM is a cellular network, which means that cell phones connect to it by searching for cells in the immediate vicinity. The coverage area of each cell varies according to the implementation environment (Mouly & Pautet, 2002). For example, macro cells can be regarded as cells where the base station antenna is installed on a mast or a building above average rooftop level. The network is structured into a number of discrete sections:

- Base Station Subsystem – the base stations and their controllers explained.
- Network and Switching Subsystem – the part of the network most similar to a fixed network, sometimes just called the "core network".
- GPRS Core Network – the optional part which allows packet-based Internet connections.
- Operations support system (OSS) – network maintenance.

Cell horizontal radius varies depending on antenna height, antenna gain, and propagation conditions from a couple of hundred meters to several tens of kilometers. The longest distance the GSM specification supports in practical use is 35 kilometers (22 mile). There are also several implementations of the concept of an extended cell, where the cell radius could be double or even more, depending on the antenna system, the type of terrain, and the timing advance.

GSM networks operate in a number of different carrier frequency ranges, GSM frequency ranges for 2G and UMTS frequency bands for 3G. Most 2G GSM networks operating in the 900 MHz or 1800 MHz bands (Timo, et al., 2004). Where these bands were already allocated, the 850 MHz and 1900 MHz bands were used instead for example in Canada and the United States. In rare cases the 400 and 450 MHz frequency bands are assigned in some countries because they were previously used for first-generation systems (Sanjay, et al., 2008).

GSM uses Frequency Division Multiplexing and Time Division Multiplexing. FDMA divides the frequency ranges for GSM, which are 890-915, 935-960 and some others that the book didn't have. Each is divided into 200 kHz wide channels. As far as TDMA goes, each time slot is 577 micro seconds long, 8 time slices is a frame, lasting for a grand total of 4.615ms. A multi frame consists of 51 frames, 51 multi frames make up a Super frame, and 2048 Super frames make a Hyper frame which is 2715648 frames (Sarika, 2013). The GSM network can be divided into three parts to illustrate this, consider figure 2.2:

- i) Mobile station.
- ii) Base station subsystem.
- iii) Network subsystem.

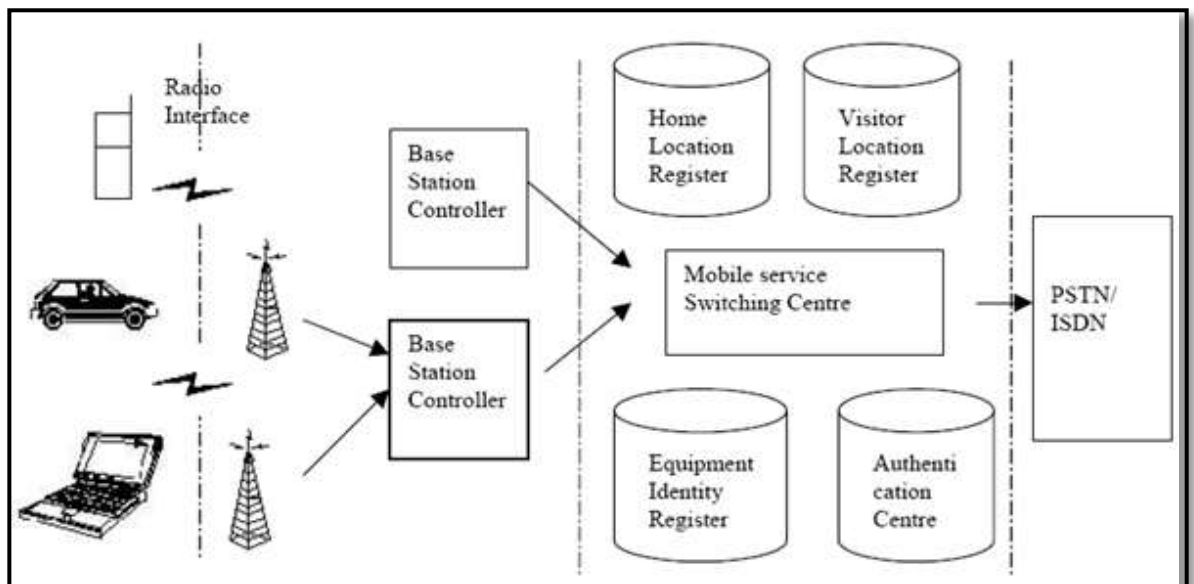

Figure 2.3: GSM Architecture

### 2.3.2 Bluetooth and Wi-Fi

Another wireless technology is Bluetooth and Wi-Fi. Bluetooth is a wireless technology standard for exchanging data over short distances using short-wavelength UHF radio waves in the ISM band from 2.4 to 2.485 GHz from fixed and mobile devices, and building personal area networks (PANs). It was originally conceived as a wireless alternative to RS-232 data cables. It can connect several devices, overcoming problems of synchronization. Bluetooth operates in the range of 2400–2483.5 MHz (including guard bands).

Wi-Fi is a technology that allows an electronic device to exchange data or connect to the internet wirelessly using 2.4 GHz UHF and 5 GHz SHF radio waves. These can connect to a network resource such as the Internet via a wireless network access point. Such an access point (or hotspot) has a range of about 20 meters (66 feet) indoors and a greater range outdoors. Hotspot coverage can comprise an area as small as a single room with walls that block radio waves, or as large as many square kilometers achieved by using multiple overlapping access points.

Bluetooth and Wi-Fi have some similar applications such as setting up networks, printing, or transferring files. Wi-Fi is intended as a replacement for high speed cabling for general local area network access in work areas. This category of applications is sometimes called wireless local area networks (WLAN) while Bluetooth was intended for portable equipment and its applications. The category of applications is outlined as the wireless personal area network (WPAN).

### 2.3.3 Radio Frequency (RF)

Radio Frequency (RF) communications is based on laws of physics that describe the behavior of electromagnetic energy waves. RF is a rate of oscillation in the range of around 3KHz to 300 GHz, which corresponds to the frequency of radio waves, and the alternating currents which carry radio signals. RF usually refers to electrical rather than mechanical oscillations. There are essentially parameters to look at when trying to determine range:

(i) Transmit power

Transmit power refers to the amount of RF power that comes out of the antenna port of the radio. Transmit power is usually measured in Watts, milliwatts or dB.

(ii) Receiver sensitivity

Receiver sensitivity refers to the minimum level signal the radio can demodulate. It is convenient to use an example with sound wave; transmit power is how loud someone is yelling and receive sensitivity would be how soft a voice someone can hear. Transmit power and receive sensitivity together constitute the link budget between the transmitter and receiver and still have communication occur.

(iii) RF communications and data rate

Data rates are usually dictated by the system such as how much data must be transferred and how often does the transfer need to take place. Lower data rates, allow the radio module to have better receive sensitivity and thus more range. In the XStream modules the 9600 baud module has 3dB more sensitivity than the 19200 baud module. This means about 30% more distance in line-of-sight conditions. Higher data rates allow the communication to take place in less time, potentially using more power to transmit.
