DECLARATION

I hereby, declared this report entitled “Power Factor Improvement using Automatic Power Factor Compensation (APFC) Device for Medical Industries in Malaysia” is the results of my own research except as cited in references.

Signature:

Author's name: MARYAM NABIHAH BINTI ZAIDI

Date: 22nd DECEMBER 2017

APPROVAL

This report is submitted to the Faculty of Engineering Technology of UTeM as a partial fulfillment of the requirements for the degree of Bachelor of Electrical Engineering Technology (Industrial Power) with Honours. The member of the supervisory is as follow:

.....
(MR ADLAN ALI)

ABSTRAK

Laporan ini membentangkan projek yang direka untuk membetulkan faktor kuasa secara automatik bagi industri perubatan di Malaysia dengan harapan untuk menjadikan penggunaan kos dan tenaga yang cekap, kerana sumber tenaga kini semakin berkurangan disebabkan peningkatan populasi. Faktor kuasa ialah nisbah kuasa sebenar dan kuasa nyata. Takrif ini secara matematik diwakili sebagai kW / kVA di mana kW adalah kuasa aktif dan kVA adalah kuasa nyata (aktif + reaktif). Kuasa reaktif adalah kuasa yang dihasilkan oleh beban magnetik dan induktif untuk menjana fluks magnetik. Peningkatan daya reaktif meningkatkan kuasa jelas supaya faktor kuasa akan berkurangan. Faktor kuasa yang rendah akan menyebabkan industri perlu memenuhi permintaan yang tinggi dan menjadikan penggunaan tenaga kurang cekap. Matlamat utama projek ini adalah untuk meningkatkan faktor kuasa semasa industri perubatan dari 0.85 hingga 0.90. Pampasan faktor kuasa menyumbang kepada pengurangan arus dan meningkatkan kecekapan tenaga sambil mengembangkan kebolehpercayaan perancangan untuk rangkaian tenaga masa depan. Apabila teknologi berkembang, penalti kos dan kecekapan yang beransur-ansur harus dikurangkan. Oleh itu, peranti pampasan faktor kuasa automatik harus menjadi alat yang kos efektif dan lebih kecil dari masa ke masa. Inilah sebabnya projek ini menggunakan peranti boleh atur kerana ia merupakan peranti binaan miniatur.

Kata kunci-faktor kuasa (pf); fluks magnet; kuasa reaktif

ABSTRACT

This paper present the project designed to correcting power factor for medical industries in Malaysia automatically. Which with hope to make the cost and energy usage efficient, because the energy source are depleting due to increase in population. Power factor is the ratio of real power and apparent power. This definition is mathematically represented as kW/kVA where kW is active power and kVA is apparent power (active + reactive). Reactive power is the non-working power generated by the magnetic and inductive load to generate magnetic flux. The increase in reactive power increase the apparent power so the power factor will decrease. Low pF will cause the industry to meet high demand thus making it less efficient. The main aim of this project is to increasing the current power factor of medical industries from 0.85 to 0.90. Power factor compensation contribute to reduction in current-dependent losses and increase energy efficiency while expanding the reliability of planning for future energy network. As technology develops, the gradual cost and efficiency penalty should reduce. Therefore, automatic power factor compensation device should become cost-effective and smaller device over time. That is the reason this project is using programmable device as it is a miniature architecture device.

Keywords—power factor (pf); magnetic flux; reactive power

DEDICATION

To my beloved parents, Puan Norshamshida Binti Mohamed Zohdi (mama) and Prof Dr Zaidi Bin Mohd Ripin (ayah) that continuously giving me support and love.

To my lovely siblings, Aminah, Harith and Sulaymann that cherish my days.

To my super-awesome supervisor, En Adlan Bin Ali who always remind me of my progress and keep on giving positive words.

To my friends, especially Afisah that helps me a lot when I'm stuck with my coding and my swag SV team members Alia, Akma and Atiq.

To En Azhan for allowing me to use the Control, Instrumentation and Mechatronic Workshop.

To all lecturers and staff that help this project directly or indirectly.

Most importantly, my biggest gratitude to The Almighty Allah swt for everything.

ACKNOWLEDGEMENT

I would like to thank my parents, my family, my supervisor and friends. I am gratefully thanks to Universiti Teknikal Malaysia Melaka (UTeM) for providing support for this paper. The authors would also want to express their thank you to all parties involved for their effortless support towards the completion of this paper.

CHAPTER 1

INTRODUCTION

1.1 Project Background

Electrical power has been proven to be one of the most important resource in Malaysia and due to its high demand and widely used, it has become a very expensive resource. The cause of its high cost is mainly because of the generation cost, transmission cost and distribution cost. Plus, the demand of commercial and industrial customers varies greatly throughout the day and for them (the industrial consumers) the maximum demand plays and important role in their overall electricity bills. Therefore, they need to ensure that their max demand is low as possible for their substantial savings. This is the main purpose of this project where it is to overcome the unwanted problem, power factor need to be improved by installing Automatic Power Factor Compensation (by adding capacitor load to offset the inductive load present in the power system). The capacitors can be installed at the service entrance of the plant or on the load side of the metering equipment. These capacitors may supply part, or all of the reactive power required by the plant. There are many benefits by having Automatic Power Factor Compensation device. For the industrial usage, the equipment will have a longer life span and the maintenance costs remain low. According to Sandesh, Singh and Phulambrikar (2012), power factor improvement leads to a huge drop of apparent power drawn from the ac source which in turn protects energy and minimizes the transmission losses.

1.2 Motivation

This project will make the consumers actually see the effect of high and low power system in their consumption of energy. When the power factor is very low, they may be able to see the effect and reach out to make the operation system change as needed. They can increase the power factor by using the automatic power factor compensation which uses capacitor and microcontroller as the main components. Thus, this will help in improving the power factor of a system. Plus, the current demand on energy is increasing day by day and the industries' growth is inclining. Plus, according to the Ministry of Health Malaysia (MoH), medical industries have been tremendously growing for the past decades, 8% to 10% annually. But on the other hand, the energy sources are depleting due to an increase in population.

1.3 Problem Statement

Power factor or wasted energy capacity is something that is often being overlooked by the consumer as it does not really give a big effect to them (referring to the residential area) as they do not have to pay any penalties from the TNB and their tariff is based on the amount of energy (kWh) used only. On the other hand, TNB imposes on all industries and large power consumption (LPC) to maintain their power factor to no less than 0.85 and failing to maintain their power will result in a penalty being imposed on them. In fact, power factor can result in poor reliability, safety problems and high energy costs as mentioned by Tagwira (2014). The lower the power factor is, the less economical the power system operates. All these problems stated are related and due to a low power factor and the current power factor produced by the medical industries (the industry this project focuses on) in Malaysia is around 0.9 and the aim is to increase it to 0.95 or nearest to unity so that it can give benefits to both the supplier and consumers.

1.4 Objective

The main objectives of this project is:

- i. To identify the most suitable software to be used.
- ii. To design a circuit for automatic operation for Power Factor Compensation.
- iii. To develop a programming code for the Automatic Power Factor Compensation (APFC) device.

1.5 Project Scope

This project is focusing on:

- i. Improving existing power factor on medical industries in Malaysia.
- ii. To ensure that power factor is more than 0.9.
- iii. To design an automatic function of the device.
- iv. To determine the value of reactive power (Q).

CHAPTER 2

LITERATURE REVIEW

2.1 Introduction

In this chapter, it emphasizes more on the important theory and assessment related to the work required in developing the project. A thorough research had been done on the factors that affect power factor and the type of corrective instruments used to execute the desired objectives. Besides, it also shows and proves how it can give benefits to the industries that use high voltage supplies.

There are two type of power factor correction which are fixed and automated, and this project focuses on the automated system. There are few main reasons why the power factor correction (or compensation) need to be automated:

- i. Stability – A stable power system means stable voltage supply and fewer faults that can reduced costs (especially in the electricity tariff).
- ii. Safety – The needs of automated controls is to ensure that the plant must be safe to operate even when there is instability of power system.

2.2 Power factor

Ware, J. (2006) described that power factor is the ratio between the useful (true) power (kW) to the total (apparent) power (kVA) consumed by an item of alternating current (A.C) electrical equipment or a complete electrical installation. It is a measure of how efficiently electrical power is converted into useful work output. The ideal power factor is unity, or one. Anything less than one means that extra power is required to achieve the actual task at hand. Power factor is expressed as a percentage (%).

$$\text{Power factor} = \frac{\text{Real power (kW)}}{\text{Total power (kVA)}} \times 100$$

Real power or true power, P is the power that is used to do work on the load. Active power is measured in *watts (W)* and in the electricity billing, it is stated in kilowatt-hours (kWh). It is the power drawn by the electrical resistance of a system doing useful work. Reactive power is the power not used to do work on the load.

Reactive power, Q is measured in volt-amperes reactive (VAR) and stored in and discharged by inductive motors, transformers or solenoids. The reactive power required by inductive loads increases the amount of apparent power and it is measured in kilovolt amps (kVA) in the distribution systems. But reactive power are not stated in the electrical tariff. Increasing the reactive and apparent power causes the power factor, PF to decrease.

Total power or apparent power is the combination of real power and reactive power. Apparent power is the power supplied to the circuit and is measured in volt-amperes (VA). Total power in the electrical billing statement is measured in volt-ampere-hour (kVAh).

Kanchi et al. (2013) have described that generally, power factor is called as the cosine of angle between the voltage and current. In an a.c circuits there is generally a phase difference between voltage and current. If the circuit is inductive, the current lags behind the voltage and the power factor is called lagging power factor and if the circuit is capacitive then current leads to voltage and power factor is said to be leading power factor.

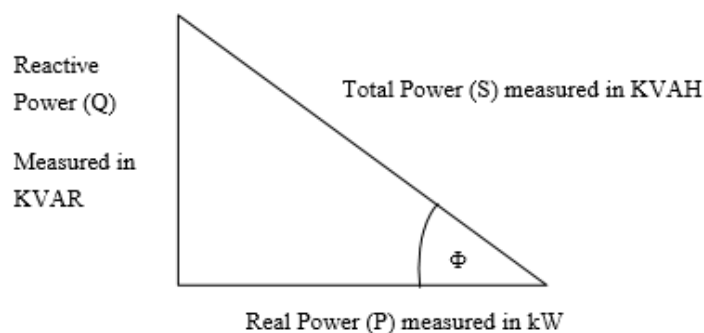

Figure 2.2.1: Power triangle (source: Tagwira, 2014)

The power factor of an alternating-current device or circuit is the ratio of the active power P to the apparent power S. Power factor is expressed as a simple number, or as a percentage. It is given by the equation

$$\text{Power factor} = P/S$$

where; P = active power delivered or absorbed by the circuit or device [W]

S = apparent power of the circuit or device [VA]

The power factor never exceed 100 percent or unity because the value of active power can never be greater than apparent power. Power factor is also a measure of the phase angle between voltage and current. Where this leads to another equation,

$$\begin{aligned}\text{Power factor} &= \frac{P}{S} \\ &= \frac{EI_p}{EI} \\ &= I_p/I \\ &= \cos \theta\end{aligned}$$

Neha Shrivastava (2015) stated that the AC circuits are made of resistive, inductive and capacitive components. For purely resistive load like incandescent lighting, the current and voltage are in phase where the current follows the voltage. For inductive loads case, the current is out of phase with voltage where it lags behind the voltage except for a few purely resistive loads and synchronous. However, in a capacitive load the current leads the voltage thus means the current and voltage are out of phase. The most common capacitive loads are the capacitors used for the correction of power factor of the load.

2.3 Power factor correction

Power factor correction can be applied by the electrical utility to improve the stability and efficiency of the transmission network or, it can be installed by the electrical consumer to reduce costs charged by the electrical provider.

Wildi, T. (2006) mentioned that power factor correction (or improvement) is economically practicable whenever the decrease in the annual cost of electricity exceed the pay back cost of installing the required capacitors. In some cases, the customer has no choice but must obey with the minimum power factor specified by the utility company. The power factor may be amended by installing capacitors at the commercial enterprise or at the service entrance of the factory. In other cases, if the power factor is particularly low, it may be necessary to correct the power factor of the device or machine individually.

Power factor compensation can be defined as a process of correcting the lagging current by producing leading current so that the angle between voltage and current reduces. There will be no power loss if the current and voltage are in phase, thus it can improve the power factor value to nearly unity or even unity. The process is done by connecting few capacitors at the service entrance where the power factor is attuned by an adequate value of capacitance.

The electrical loads that work on alternating current need apparent power which is the product of real power and reactive power. The reason why the electrical load has power factor less than one is, the existence of reactive power makes the apparent power higher than real power. The reactive power increases the current flow from the power sources and the load. When this happens, power losses increases in both distribution and transmission lines. Thus, this results in financial losses for the power provider like Tenaga Nasional Berhad (TNB) which made them require their consumers and customers, especially those who use large loads to maintain their power factor above 0.85 or higher.

Besides the increased in operation costs, reactive power requires the use of higher current capacitance components like wires, switches, transformer and circuit breakers. Power factor can be improved by few methods such as installed capacitor banks in parallel, synchronous condenser and phase advancer.

2.3.1 Passive power factor compensation

Passive PFC needs larger inductor than active PFC but it still cost less. This is an easy way to correct the nonlinearity in a load by using capacitor bank but it is not as effective as active PFC. According to Amin (2012), the simplest way to control the harmonic current is to use a filter: it is probable to design a filter that passes current only at line frequency (50 or 60 Hz). This filter decreases the harmonic current, which means that the nonlinear device now looks like a linear load. At this point the power factor can be conveyed to near unity, using capacitors or inductors as requisite. This filter needs large-value high-current inductors which are huge and costly. Passive PFCs are typically more power efficient than active PFCs. A passive PFC on a switching computer PSU has a typical power efficiency of around 96%, while an active PFC has a typical efficiency of about 94%.

2.3.2 Active power factor compensation

Active PFC is a power electronic system that modified the wave shape of current drawn by a load to correct the power factor. The reason is to make the power factor corrected appear purely resistive so that the voltage and current are in phase and the reactive power consumption is zero. This allows the most efficient distribution of electrical power from the power company to the consumer. There are few types of active PFC which are Boost, Buck and Buck-boost. Amin (2012) also mentioned that the active power factor correctors can be single-stage or multi-stage. In the case of a switched-mode power supply, a boost converter is inserted between the bridge rectifier and the main input capacitors. The boost converter efforts to keep a constant DC bus voltage on its output while drawing a current that is always in phase with and at the same frequency as the line voltage. Another switch mode converter inside the power supply produces the preferred output voltage from the DC bus. This method needs extra semiconductor switches and control electronics, but permits inexpensive and smaller passive components. It is normally used in practice due to their very wide-ranging input voltage, many power supplies with active PFC can automatically alter to operate on AC power from about 100 V (Japan) to 230 V (Europe). That feature is mostly wanted in power supplies for laptops.

2.4 TNB power factor surcharge

According to Tenaga Nasional Berhad (TNB), for customers taking supply at 33 kV or below, the value of the power factor to be retained is more or equal to 0.85. For customers taking supply at 132 kV or above, the value of the power factor to be retained is more or equal to 0.90. If the consumers cannot oblige the value needed, they will be penalised by the power provider in power factor surcharge. A high Power Factor index (e.g. above 0.85 or 0.90) indicates an efficient level of electricity usage. On the other hand, a low Power Factor index (e.g. under 0.85 or 0.90) shows an inefficient use of electricity, indicating electricity wastage.

Plus, according to Ministry of Energy, Green Technology and Water (KeTTHA) regulates the electricity tariffs charged by the utilities to final consumers in Peninsular Malaysia and Sabah in pursuance of the Electricity Supply Act 1990. Among the principles applied in determining tariff rate is:

- The tariff should reflect the cost supply.
- Provide adequate revenue for the development of the power sector.
- Competitiveness among the industries and services.
- Affordability of the consumers and social economic objectives of the government.

TNB imposes on all industrial and low power consumer to maintain their power factor to no less than 0.85. Failing to maintain the required PF will result on a penalty being imposed on them. The penalty is incorporated into the tariff structure. The consumer should use their best endeavours to obtain highest possible in PF in the operation of any of their electrical installation. Based on TNB, power factor below 0.85 and up to 0.75 ($0.85 > PF \geq 0.75$) lagging, a supplementary charge 1.5% of the bill for the month for each 0.01 unit below 0.85 and up to 0.75 lagging PF will be added to the bill for that month. On the other hand, power factor below 0.75 lagging, in addition to the charge payable under the above condition, a supplementary charge of 3% of the bill for that month for each 0.01 unit below 0.75 lagging PF will be added to the bill of the month.

Effectively, on 1st June 2011, the electricity tariff was reviewed. It is structured to balance between protecting low income group and sustaining the nation's

competitiveness. Prior to that, the last review was carried out in 1st March 2009. The electricity tariff rate are based on the following guideline:

- The amount of energy consumed (kWh)
- The maximum demand at which energy consumed (kW)
- Peak or off peak period
- The power factor of the load
- The connected load

The explanations on load and power factor surcharged can be proven or showed by a simple example which is to make a comparison between two different factory (indicates the industry). Consider two factories A and B consume the same amount of energy (kWh) and have the same maximum demand (kW). However, the power factor of A is unity (1) while B is 0.5.

Factory A

Maximum demand = 1000 kW
Apparent power = 1000 kVA
Power factor = 1.0
Current bill = RM 3000

Factory B

Maximum demand = 1000 kW
Apparent power = 2000 kVA
Power factor = 0.5
Current bill = RM 4000

From the equation of apparent power, ($S = I.V$) it can be seen that the line current proportional to the apparent power and factory B draws twice as much current as factory A. The line conductors, transformers, circuit breakers, and other devices supplying energy to B must have twice the rating to those supplying to A. Besides, the utility company must invest more capital to factory B; consequently it is logical that

factory B should pay more for its energy, even though it consumes the same amount. As for the TNB power factor surcharged,

- Factory A

POWER FACTOR	= 0.60
SURCHARGE	= No surcharge as the PF is above 0.85
TOTAL BILL	= RM 3000.00

- Factory B

POWER FACTOR	= 0.50
SURCHARGE	$= \left[\frac{0.85 - 0.75}{0.01} \times 1.5\% \times 4000 \right] + \left[\left(\frac{0.75 - 0.5}{0.01} \times 3\% \times 4000 \right) \right]$
TOTAL BILL	= RM 6600.00

From the example shown, it can be seen that low power factor will cause the industry to be penalised by TNB and this will make them spend more just to settle their penalty. Therefore, rather than paying higher monthly bill, the power factor should be improved or corrected by using a suitable power factor compensation method.

2.5 The uses of capacitors in APFC

Capacitors are widely used in electronic circuits for hindering direct current while permitting alternating current to pass, in filter networks, for smooth out the output of power supplies. An automatic power factor correction unit have a number of capacitors that are switched by means of contactors. These contactors are controlled by a regulator that measures power factor in an electrical network or individual motors. This assures that only the needed capacitor is energized depending on the load and power factor of the network to ensure the power factor remains above a selected value. For this type of application, usually a fixed capacitor is used because it is the simplest and cheapest way of power factor correction, based on Tagwira (2014) research.
