DEDICATIONS

I would like to give thanks to my family members who give full support for my education, beloved supervisor and panel who encourage me and guided me with their knowledge throughout this research and coursemates who have shared their experience in order to help me complete this research.

ACKNOWLEDGEMENTS

In preparing this report, I was in contact with many people, researchers, academicians and practitioners. They have contributed towards my understanding and thought. In particular, I wish to express my sincere appreciation to my main project supervisor, Mdm Azrina binti Othman, for encouragement, guidance critics and friendship. I am also very thankful to my co-supervisors Dr. Norhidayah binti Mohamad for her guidance, advices and motivation. Without their continued support and interest, this project would not have been same as presented here.

My fellow postgraduate students should also be recognized for their support. My sincere appreciation also extends to all my colleagues and others who have provided assistance at various occasions. Their views and tips are useful indeed. Unfortunately, it is not possible to list all of them in this limited space. I am grateful to all my family members.

ABSTRACT

The digital economy grew dramatically in 2020 as a result of the COVID-19 pandemic, which spawned new digital businesses, prompted conventional brick-and-mortar businesses to go online, and millions of Malaysians to purchase online. E-commerce sites are reaping the benefits of this revolutionary technological improvement due to the latest developments in the digital world. Regardless of industry, machine learning can provide numerous benefits to owners of large and small businesses. Nevertheless, practically all customer interactions are digital, and while e-commerce companies have collected enormous amounts of customer data, it is difficult to bring it all together and provide actionable insights for marketing decisions. Therefore, this research aims to determine the impact of machine learning applications on e-commerce. The researcher collect data from 10 members from each of the top 20 e-commerce sites in Malaysia who are aware with the applications of machine learning in e-commerce. Then, the researcher analyze data by using Statistical Package of Social Science (SPSS) Version 26. From the results of the questionnaire was conducted the researcher can found that there were positive relationships between recommendation systems, customer relationship management, fraud detection and the impact of machine learning applications on e-commerce performance.

Keywords: E-commerce, machine learning, application, technology

ABSTRAK

Ekonomi digital berkembang secara mendadak pada tahun 2020 akibat daripada pandemik COVID-19, yang melahirkan perniagaan digital baharu, mendorong perniagaan konvensional untuk pergi ke dalam talian, dan berjuta-juta rakyat Malaysia membeli dalam talian. Tapak e-dagang mendapat manfaat daripada peningkatan teknologi revolusioner ini berikutan perkembangan terkini dalam dunia digital. Tidak kira industri, pembelajaran mesin boleh memberikan banyak faedah kepada pemilik perniagaan besar dan kecil. Namun begitu, hampir semua interaksi pelanggan adalah digital, dan walaupun syarikat e-dagang telah mengumpulkan sejumlah besar data pelanggan, adalah sukar untuk menyatukan semuanya dan memberikan pandangan yang boleh diambil tindakan untuk keputusan pemasaran. Oleh itu, penyelidikan ini bertujuan untuk menentukan kesan aplikasi pembelajaran mesin terhadap e-dagang. Pengkaji mengumpul data daripada 10 ahli daripada setiap 20 tapak e-dagang teratas di Malaysia yang mengetahui tentang aplikasi pembelajaran mesin dalam e-dagang. Kemudian, pengkaji menganalisis data dengan menggunakan Statistical Package of Social Science (SPSS) Versi 26. Daripada hasil soal selidik yang dijalankan pengkaji dapati bahawa terdapat hubungan yang positif antara sistem pengesyoran, pengurusan perhubungan pelanggan, pengesanan penipuan dan kesan aplikasi pembelajaran mesin mengenai prestasi e-dagang.

CHAPTER 1

INTRODUCTION

1.1 Introduction

This chapter discussed the background of the study, problem statement, research questions, research objectives, scope and limitations of the study, significant of study and summary of the whole chapter.

1.2 Background of Study

The digital economy has grown rapidly in 2020 because the COVID-19 pandemic spawned new digital businesses, forced traditional business with physical premises turn to online, and millions of Malaysians also purchase online. (Malaysia Digital Economy Blueprint, 2022). Although e-commerce has been around for several decades, its performance in today's world is based on artificial intelligence rather than business intelligence (Behgounia and Zohuri, 2022). Furthermore, with the evolution of artificial intelligence (AI) and its subfield machine learning (ML), as well as technological integration with the majority of modern e-commerce platforms, we could also see more and more physical stores are migrating to the online. Thus, e-commerce sites are reaping the benefits of this revolutionary technological improvement due to the latest developments in the digital world.

Moreover, with the transition from traditional to modern technologies and the use of digital technologies, most e-commerce is now based on revolution and creative improvements, such as automation (Behgounia and Zohuri, 2022). Today, AI is in high demand, from AI-powered search engines to self-driving cars. It is the process by which machines, such as computer systems, can perform jobs that require human intelligence, which involves learning, reasoning and self-modification to drive the process (Yap, 2021). No matter in which industry, machine learning can provide numerous benefits to both large and small business owners. It can help produce better services, identify problems and reduce risks, better understanding of consumer behavior, and make better decisions sales and marketing.

Machine learning is an artificial intelligence (AI) application that allows systems to automatically learn and improve experiences without direct human help or intervention, and then make decisions based on that learning (Kumar, Ramachandran, & Kumar, 2021). Nowadays, customers want more personalized and better experience during their customer journey. Nevertheless, practically all customer interactions are digital, and while e-commerce companies have collected enormous amounts of customer data, it is difficult to bring it all together and provide actionable insights for marketing decisions. However, machine learning can precisely forecast what customers want and thereby increase sales by evaluating customer data. Therefore, the researcher needs to determine the impact of machine learning applications on e-commerce performance.

1.3 Conceptual & Operational Definition of Study

1.3.1 Conceptual Definition

The field of machine learning involves the design of programs that learn rules from data, adapt to changes, and improve performance based on experience. Besides, machine learning also refers to the techniques that required to operate intelligently with enormous amounts of data, such as synthesizing, classifying, or sorting this data. (Micu et al., 2021).

1.3.2 Operational Definition

Hua (2016) defined e-commerce as a sophisticated information technology (IT) process that helps in the achievement of a comprehensive consumer experience through design, communication, fulfilment, distribution and evaluation. Besides, Hua (2016) also defined e-commerce performance as the business value impact of e-commerce, which encompasses three types of benefits: marketing and competitive advantages, fundamental advantages that support strategy and development, and business efficiency advantages.

In this research, the researcher defines machine learning as an algorithm used to make an improvement to the systems in e-commerce. The systems including fraud detection, Customer Relationship Management (CRM) system, and recommendation system in e-commerce. These machine-learning algorithms will be compared in order

to determine the best accuracy results from the e-commerce transaction dataset (Saputra et al., 2019). In addition, the researcher defines e-commerce as sites for the purchasing and selling of products and services over electronic networks.

Furthermore, the researchers defined e-commerce performance as how e-commerce sites serve shoppers more effectively and thus increase sales. Machine learning models can help CRM systems analyze customer personal and behavioral data to give companies a competitive advantage by improving customer retention. These models can forecast which consumers will churn and reasons why they churn (Sahar, 2018). According to Tahir et al. (2021), machine learning algorithms have been used to improve prediction accuracy and solve data sparseness and cold start problems when creating recommendation systems. Therefore, machine learning can help in increasing sales and optimizing many features of e-commerce operations, such as product selection and ordering. According to Areiqat et al (2021), machine learning in e-commerce will have an impact on transactions, customer retention, and satisfaction.

1.4 Problem Statement

Malaysia's e-commerce revenue increased 17.1 percent year on year to RM279 billion in the third quarter of 2021, up from RM238.2 billion in the previous quarter. According to the finding of the Malaysia Digital Economy (2021), e-commerce revenue surged by 4.3 percent quarter on quarter. Chief statistician Datuk Seri Dr Mohd Uzir Mahidin responded to this finding by stating that the improved performance was due to the adoption of the new normal during the COVID-19 pandemic, which increased digital usage in Malaysia. As online shopping becomes increasingly widespread, one of the possible problems for many e-commerce platforms is customers information overload. Therefore, e-commerce companies must implement machine learning recommendation systems to improve the accuracy of predictions that best meet customer demands and preferences (Tahir et al., 2021). Besides, Sharma (2021) pointed out that artificial intelligence is the foundation of e-commerce development, and machine learning is a sub-field of artificial intelligence, has been widely used in e-commerce to collect data from customer. This is because by collecting the data from customer, enabling e-commerce to predict customer behavioral pattern and recommend products that meet their needs and preferences

(Sharma, 2021). Therefore, the development of e-commerce business highlights the necessity of establishing an effective recommendation system in this era.

According to InMobi research, 26 percent of Southeast Asian consumers have determined what categories they want to shop for but have not yet narrowed down on specific products or brands during shopping journey (Saurabh Madan, 2022). Thus, Customer Relationship Management (CRM) is required for the companies to get a better understanding of their customers and gain customers' satisfaction. CRM is the supporting systems that support a strategy aimed at developing profitable long-term relationships and interactions with customers and potential customers. Consequently, CRM is crucial for any company because acquiring new customers is more expensive than retaining existing customers (Vlačić et al., 2021). By utilizing business intelligence and analytical models, CRM systems may identify the most profitable set of customers and target them in order to achieve higher customer retention rates. Furthermore, many types of machine learning techniques have been widely employed to assess the probability of customer churn (Sabbeh, 2018).

Furthermore, it is critical to improve customers' transaction experience when shopping online by utilizing machine learning to prevent fraudulent transactions on e-commerce (Raiter, 2021). As of October 31, Malaysia had recorded 8,162 cases of e-commerce fraud with a total loss of 57.73 million ringgit (Mahalingam et al., 2021). Fraudsters simply require a few bits of information, such as security codes, credit card numbers, expiration dates, and so on, to conduct fraudulent transactions using online payment methods. As a result, the development of fraud detection algorithms is important in order to avoid losses, and a rising number of algorithms rely on advanced machine learning technology to assist fraud detectors (Kumar et al., 2021). Thus, this research aims to investigate the relationship between the impact of machine learning applications on e-commerce performance.

1.5 Research Question

RQ1: What are the applications of machine learning in e-commerce sites?

RQ2: What is the impact of machine learning applications on e-commerce performance?

RQ3: What is the relationship between the impact of machine learning applications on e-commerce performance?

1.6 Research Objective

RO1: To determine the applications of machine learning in e-commerce sites.

RO2: To examine the impact of machine learning applications on e-commerce performance.

RO3: To investigate the relationship between the impact of machine learning applications on e-commerce performance.

1.7 Scope and Limitation of Study

This research focused on the impact of machine learning applications on e-commerce performance. Additionally, it also focused on the applications of machine learning in e-commerce sites. Moreover, the research scope is to identify the applications of machine learning that affect e-commerce performance. The researcher's target respondents in this research are employers and employees that used machine learning applications in their ecommerce platform. The researcher distributed the questionnaire to the target respondents via an online survey, such as Google Form.

The limitation of this study is only focusing on the applications of machine learning in e-commerce. Therefore, this study cannot cover all the other industries because the research is only limited to the e-commerce industry, so the outcomes of literature, theoretical proposition, data analyzed, and conclusions made can only be generalized to the e-commerce industry. In addition, the applications of machine learning in other industries have different impacts, therefore, the results of this study cannot be considered as the impact of the applications of machine learning on all industries.

1.8 Significance of Study

First, by conducting this research, the researcher can understand clearly on the impact of machine learning applications on e-commerce performance. Moreover, the researcher also can clarify the relationship between the impact of machine learning applications on e-commerce performance. Thus, this study would help more and more e-commerce comprehend the impact of machine learning applications on its performance. Through the applications of machine learning can improve the business performance and it indirectly increase the profit of companies. In addition, this research can act as future reference for other researcher that plan to conduct research that relate with the impact of machine learning applications on e-commerce performance.

1.9 Summary

The framework of this chapter is a general introduction to the research. The topic selection of this research is introduced, including research background, research concept and operational definition, problem statement, research question and research purpose, research scope and limitations, and research significance.

CHAPTER 2

LITERATURE REVIEW

2.1 Introduction

This chapter discussed the literature review of this research. The researcher explained the definition of machine learning (ML) and e-commerce, the applications of machine learning, and the impact of machine learning applications towards e-commerce. In addition, the dependent and independent variables are defined in order to develop the hypotheses. At the end of this chapter, the researcher developed a conceptual framework to explain the research.

2.2 Technology

According to Christiansen et al. (2011), Technologies are divided into three broad categories: hardware, software, and orgware. Hardware refers to physical tools and devices; Software refers to the skills, knowledge and processes involved and required to use technology; Orgware (or organizational technology) refers to the ownership of technology or the institutional arrangements by which organizations or communities will use technology.

Besides, Miao et al. (2022) also stated that the emergence and development of artificial intelligence and other emerging technologies have not only created new industries and changed the global competitive landscape, but also changed people's lives and the way of social and economic production. Technology is an enabler and motivator of change, but change must be driven by business drivers who leverage technology. E-commerce technology has brought about significant changes in the way business operates (Bajaj et al., 2005).

According to Geum, Kim, & Lee (2017), technology in service businesses differs from technology in manufacturing businesses. Manufacturing technologies are directly applied to new product development, either to provide goods with more and

diverse features or to contribute to faster and more efficient new product development operations. However, service technologies vary in purpose, role and application area, and act as facilitators for employees and consumers to provide customized services that enable service operations to be more efficient, thereby increasing customer satisfaction.

2.3 Machine Learning (ML)

According to Kumar et.al (2019), machine learning is an application of artificial intelligence that enables computers automatically to learn and improve from experience without explicit programming. It also focuses on the creation of computer programmes capable of accessing data and using it to learn for themselves. Furthermore, it is a method of training an algorithm to learn how to make decisions. Machine learning has grown dramatically in recent years in the context of data analysis and computation, allowing applications to work intelligently (Sarker, 2021).

Besides, Athey (2019) also stated that the field of machine learning is concerned with the development of algorithms for application in data sets, with the key areas of concentration being prediction (regression), clustering, classification, and grouping tasks. Machine learning is classified into four types, involving supervised learning, unsupervised learning, reinforcement learning, and semi-supervised learning (Hua, 2008). In addition, machine learning can be defined as a theory that allows a computer to learn how to accomplish a task. Meanwhile there is no need for the computer to be programmed. Machine learning is concerned with the analysis and development of algorithms. These algorithms can learn any skill and make predictions based on data (Medar, Rajpurohit & Rashmi, 2017).

According to Wang, Ma, & Zhou (2009), Machine learning is the study of using computers to simulate human learning processes. It is also the study of computer self-improvement strategies, including the acquisition of new knowledge and capabilities, the discovery of existing knowledge, and the continuous improvement of performance and achievement. Machine learning is faster than human learning because it is easier to gather knowledge and disseminate learning results. Therefore, every
