Supervisor Name : DR NUZAIMAH BTE MUSTAFA
Date : 27 January 2023

DEDICATION

To my beloved mother and father thank you for always supporting me throughout this
Final year project.

To my supervisor, Dr NUZAIMAH BTE MUSTAFA who always help me finish
this project and always make sure I am on the right track and following all the formats for
this report.

Assalamualaikum, first thanks to Allah SWT because with HIS grace I was able to
complete this final project on time. Also, thank you to both my parents Halim Bin Ms Isa
and Naemah Binti Ali Stork for always supporting everything I do in life.

Thank you for helping me a lot to become someone who can do everything if there
is effort. Thank you for funding my studies a lot since I was from semester 1. For this final
project, they also spent a lot of money to realize the product that I created for this final
project.

Not forgetting also to my Supervisor, Dr Nuzaimah for always patiently waiting for every
progress from me. thank you for understanding me and always giving me words of
encouragement so that I don't give up. Thank you for the encouragement and guidance of

Dr, I was able to complete this project on time.

ABSTRACT

The goal of this research was to investigate the effect of MAPE as a compatibilizer on the morphological, mechanical, and physical properties of 3D printing filaments made from wood dust and recycled polypropylene (R-WoPPc). Four R-WoPPc filaments with MAPE loadings of 0%, 1%, 3%, and 5% by weight were produced and printed into 3D specimens. The morphology of R-WoPPc filament was studied, as well as the properties of printed specimens such as tensile properties, flexural properties, microstructure, and physical properties. The results revealed that 1% MAPE in R-WoPPc yielded the highest performance for the material's microstructure, tensile strength, water absorption, and flexural strength. Tensile strength improved by 74.07% compared to without MAPE addition and was the highest among all MAPE loadings. The MAPE strengthened the adhesion between recycled wood dust and recycled polypropylene matrix, resulting in improved R-WoPPc performance. Pure addition of filler and matrix causing pure properties or strength.

ABSTRAK

Matlamat penyelidikan ini adalah untuk menyiasat kesan MAPE sebagai penyerasi terhadap sifat morfologi, mekanikal dan fizikal filamen cetakan 3D yang diperbuat daripada habuk kayu dan polipropilena kitar semula (R-WoPPc). Empat filamen R-WoPPc dengan muatan MAPE sebanyak 0%, 1%, 3% dan 5% mengikut berat telah dihasilkan dan dicetak ke dalam spesimen 3D. Morfologi filamen R-WoPPc telah dikaji, serta sifat spesimen bercetak seperti sifat tegangan, sifat lentur, struktur mikro, dan sifat fizikal. Keputusan menunjukkan bahawa 1% MAPE dalam R-WoPPc menghasilkan prestasi tertinggi untuk struktur mikro bahan, kekuatan tegangan, penyerapan air dan kekuatan lenturan. Kekuatan tegangan bertambah baik sebanyak 74.07% berbanding tanpa penambahan MAPE dan merupakan yang tertinggi di antara semua beban MAPE. MAPE mengukuhkan lekatan antara habuk kayu kitar semula dan matriks polipropilena kitar semula, menghasilkan prestasi R-WoPPc yang lebih baik. Penambahan tulen pengisi dan matriks menyebabkan sifat atau kekuatan tulen.

ACKNOWLEDGEMENTS

In the Name of Allah, the Most Gracious, the Most Merciful

I would want to begin by thanking and praising Allah the Almighty, my Creator and Sustainer, for all that I have received from the beginning of my existence. I would like to thank the Universiti Teknologi Malaysia Melaka (UTeM) for providing the platform for study. The Malaysian Ministry of Higher Education (MOHE) is also thanked for the financial help.

My deepest gratitude goes to my primary supervisor, Dr. Nuzaimah Bte Mustafa, for all his assistance, counsel, and motivation. His steadfast patience in mentoring and imparting invaluable insights will be remembered forever. In addition, I would like to thank my co-supervisors, Drs. Yusliza and Syahbudil, for their unwavering support.

Lastly, I would want to thank my parents, Halim Bin Md Isa and Naemah Binti Ali, for their unwavering support and encouragement throughout my life. My eternal affection also extends to my four siblings, including Mohd Haikal bin Halim, who lends me his car and other critical items whenever I need them, and my other three siblings. I would also want to thank my family for their everlasting support, affection, and prayers. Lastly, I would want to convey my appreciation to everyone, especially my friends, who has assisted, encouraged, and motivated me to continue my education.

CHAPTER 1

INTRODUCTION

1.1 Background

In our modern era, additive manufacturing, also known as 3D printing, has advanced significantly in the recent decade. When compared to subtractive manufacturing, it has various advantages, including the capacity to make complicated forms and products without the use of specific equipment or molds. As a result, it will be great for prototyping and customizing items. FDM is a popular method of 3D printing. FDM printers fuse filament and print products layer by layer, as the name implies. There are filaments of many types, including bio-composite filaments. Due to their inexpensive price, extensive availability, high strength-to-weight ratio, high aspect ratio, and high strength and elasticity modulus, bio composite filaments are an excellent alternative to synthetic filaments (Deb & Jafferson, 2021).

The invention and testing of eco-friendly and recyclable materials such as wood, cellulose, sugars, and lignin has created a lot of interest in biodegradable 3D printing. Fiber, particle, and nanocomposite reinforced materials have also sparked interest, and several materials containing wood particles have recently hit the market. For 3D printing with wood, fused deposition modelling (FDM), injection powder printing, and liquid/paste deposition modelling have all been employed (Rafiee et al., 2021).

Natural fibers are increasingly being used as reinforcing charges in polymeric materials due to their technological advantages, environmental benefits, and economic benefits. Natural fibers are rapidly being viewed as a viable alternative to synthetic fibers due to their diversity, availability, and renewability. But however, it's hydrophobic its compatibility with the

polyolefins and/or elastomers, necessitating surface modification via treatment with chemicals or the application of coupling agents, which aid in improving interfacial adhesion with the polymer hydrophobic matrix (Palacio et al., 2020). Because the bonding strength between wood fiber (polar-hydrophilic material) and polyolefin (non-polar-hydrophobic polymers) is inadequate, a compatibilizer (coupling agent) must be added to improve the bonding strength between the wood fiber and the polymer matrix. There has been a lot of research towards optimizing the interface between wood fiber and polymer. Maleic anhydride-grafted polymer is one of the most useful coupling agents for WPC (Yuan et al., 2008).

The goal of this study, which used MAPE as a coupling agent, was to see if esterification was a significant factor for interfacial adhesion mechanisms of ultra-highly packed wood fiber polyethylene composites (UH-WPCs) based on existing findings. Furthermore, UH-WPCs were effectively extruded utilizing HDPE or MAPE as the polymer matrix at various wood fiber percentages. The mechanical characteristics, creep behavior, water absorption, and surface contact angle of UH-WPCs with and without MAPE were compared. The interfacial adhesion mechanism of UH-WPCs was studied using polymer matrix blends and wood fiber isolated from the UH-WPCs (Hao et al., 2021). Several investigations have been conducted to enhance the composite's strength. As a coupling agent in WPCs, maleated polyolefins (MAPE and MAPP) are frequently used. Adding 1% to 5% MAPE or MAPP to the mix can improve the mechanical properties (r-WoPPc).

As a coupling agent in recycled polypropylene (PP) and wood dust fiber (WDF), the maleated polyethylene (MAPE) was studied. The incorporation of MAPE was carried out during the mixing stage. The effect of the MAPE content on composite of (r-WoPPc) compatibility was analyzed.

1.2 Problem Statement

In today's advance age, it has come into existence about rapid development in additive manufacturing or 3D printing technology to be used in designing and for production sectors. However, there are still some problems that which may stem from 3D printing plastic waste where this is possible can affect the eco system such as waste of the polypropylene polymer. This is because it is non degradable property. Other than that, many wood dust residues are left unattended without knowing that the wood dust fiber can be recycled and made into filaments.

Secondly, the characteristic of the product that be produced by some of the common plastic filament which is PLA and ABS have some weakness. The filament from each material was low of the fatigue resistance. Overall, this can cause the product are easily to crack in certain part due to absorb high impact on it. Same goes to the composite filament which is the enhancing the bonding strength between the wood fiber and polymer are not strong enough without the agent coupling or compatibilizer.

1.3 Research Objective

The aim of this research is to study the physical, mechanical, and morphological properties of recycle polypropylene (PP) and recycle wood dust as reinforcement natural fiber by adding maleated-anhydride-grafted polyethylene (MAPE).

Specifically, the objective as follows:

- a) To characterize morphological properties of r R-WoPPc filament on different MAPE loading.
- b) To evaluate the effect of the different MAPE loading toward mechanical properties of the 3D printing R-WoPPc specimen.
- c) To investigate the physical properties of 3D printing R-WoPPc filament on different MAPE loading.

1.4 Scope of Research

The scope of this research is as follow:

- a) Testing and analyze physical, morphological, and mechanical of recycle of wood dust and polypropylene composite by using MAPE.
- b) Develop alternative material for 3D printing filament based on combination of Polypropylene (PP), Wood dust Fiber, and maleated-anhydride-grafted polyethylene (MAPE).
- c) Material that used in this study was wood dust, recycle polypropylene and MAPE with loading 1%, 3% and 5%.

CHAPTER 2

LITERATURE REVIEW

2.1 Introduction

The section begins by providing essential of the 3D printing process theory and also common plastics in use today that is using in the production of the 3D printing filaments. Next, I'll go over the natural fiber and composite materials used in 3D printing that are already on the market. Second, some relevant information about the materials under consideration for this work, which is a coupling agent maleic anhydride grafted polyethylene (MAPE) for natural fibers with a focus on recycled PP or PP (Polypropylene), is reviewed. In addition, in-depth look at the manufacturing procedure used in the filament's production was provided, goes as well for some theoretical information on the other method employed in the experiment.

2.2 3D Printing

2.2.1 3D Printing History

(Shahrubudin et al., 2020) found that additive manufacturing, often known as 3D printing, is a method of fabricating tangible objects out of computer models by gradually adding materials to the models. 3D printing is increasingly commonplace all around the world. In the fields of agricultural, healthcare, automotive, locomotive, and aviation, 3D printing is rapidly being utilized for mass customization and manufacture of open-source designs of all kinds. Layer-by-layer deposition of material is utilized in 3D printing to construct an object directly from a computer-aided design (CAD) model. Charles Hull pioneered 3D printing, commonly known as "Stereo-lithography," in the 1980s. This technology interprets data in CAD files (Computer Aided Design) and allows them to be electronically transformed to 3D

printers using the ".stl" format (Šramka & Ružický, 2016). By layering materials, 3D printing may turn a geometric representation into an actual thing. Since it was first commercialized in 1980, 3D printing technology has advanced at a breakneck pace. Since then, complicated walls, endodontic guides, athletic shoes, aviation engine parts, and tumor repair have all been created using this method (Shahrubudin et al., 2019).

Additive Manufacturing is another word for 3D printing. In the early 1980s, additive manufacturing was mostly used to create prototypes, but due to its precision, repeatability, and low production costs, its popularity has grown in recent years. FDM is a 3D printing method created by Stratasys in 1989. According to them, in a 3D printer, the extruder nozzle melts the filament in the heat sink before extruding it via the feeder, which feeds the filament through a nozzle (Shaik et al., 2021). Since Charles Hull's thoughts about a computer system based on stereolithography that uses the STL file format to understand data in a CAD file in 1984, many types of 3D printers have been deployed. The STL file contains information like as the color, texture, and thickness of the object to be printed, among other things. Numerous printing machines have been designed to print a wide range of things in different sectors (such as food and automotive) on a variety of scales (Shahrubudin et al., 2020).

To summarize, according to (Lee et al., 2017) was demonstrated that in the recent past, 3D printing application has emerged as a technology that is both diverse and powerful in the advanced manufacturing industry. Many countries, notably in the manufacturing sector, have adopted this technology.

2.2.2 3D Printing Process

(Šramka & Ružický, 2016) noted that the term 3D printing initially referred to a technology developed by scientists at the Massachusetts Institute of Technology (MIT) in 1993 and licensed to several companies. Today, the phrase is used to describe several processes that are all related. Designing using a computer (CAD) is at the heart of them all. CAD software
