Special dedicated to my supervisor, my parents, family and fellow friends, who had strongly encouraged and supported me in my entire journey of learning.

ACKNOWLEDGEMENT

I appreciate everyone that helped me when I faced problem in writing the matlab source code in this project. Finally I finish implement my Bachelor Degree Project 2 (PSM 2) and write my PSM report. I also want to say thanks to advice and support from my supervisor, Dr. LIM KIM CHUAN. He helped me a lot and spare times to teach me in, matlab coding, proposing title, writing report, advise for project presentation and INOTEK preparation. I want to thank to my parents, and my siblings who always support me in the entire journey of my project. Lastly, I appreciate Faculty of Electronics and Computer Engineering (FKEKK) for giving me a chance to implement my project as part of the Bachelor program in Universiti Teknikal Malaysia Melaka (UTeM).

ABSTRACT

Video conferencing involved real-time video communication between users present at two different locations. The video, consists of both the image frames and voice, are captured and compressed by a computing unit before the transmission. Coughing produced unpleasant sound while communicating through video conferencing and human being tend to cover their mouth with hand to reduce the volume of the produced unpleasant sound. The possibility of detecting the action of covering the mouth and automatically mute the input audio to suppress the noise produced by coughing is explored in this project.

The process of detecting the action of using the hand to cover the mouth, with an image processing approach, can be divided into three steps, namely the human skin pixel classification, skin region extraction and the mouth detection within the extracted skin region. Gaussian Mixture Model (GMM), Bayesian method and Multi Layer Perceptrons (MLP) are three well known methods for skin classification. GMM has been chosen due to the requirement of less memory space compare to Bayesian method and lesser computational cost compared to MLP. Experiment should that reliable human skin classification is needed to produce good result in mouth detection within the classified skin region.

Connected component labeling, one of the general region extracting algorithm provided by most of the image processing toolkit, was used to extract the skin region formed by the classified skin pixels. Making use of the extracted region, the region with seven hollows (two eye browns, two eyes, two nostrils, one mouth) is subsequently detected as “face with mouth detected”. The region with only six hollows is detected as “face with mouth not found” and a signal is subsequently send to the system to mute the

input audio. This allows the coughing noise to be automatically suppressed. The system will send a signal to unmute the input audio when “face with mouth detected” is sensed in the future image frame.

Making use of the three identified component, a software prototype has been designed and implemented. Result show that the implemented system is only able to detect both the “face with mouth detected” and “face with mouth covered by hand” in an ideal situation with around 5 frames per second.

ABSTRAK

Sidang video melibatkan penghantaran data video secara berterusan diantara dua pengguna atau lebih yang berada di tempat berlainan. Video mengandungi bingkai imej dan bingkai suara, ditangkap dan dimampatkan oleh unit pengkomputeran sebelum proses penghantaran. Batuk menghasilkan bunyi yang tidak menyenangkan semasa berbualan melalui sidang video dan manusia mempunyai tabiat untuk menutup mulut dengan tangan supaya mengurangkan nade yang tidak menyenangkan itu. Kebolehan mengesan tingkah laku untuk menutup mulut dan secara automatik menghalang kemasukan audio untuk mengurangkan kesan hingar yang dihasilkan oleh batuk telah dikaji dalam projek ini.

Proses yang melibatkan mengesan tingkah laku menutup mulut dengan pendekatan pemprosesan imej boleh dibahagikan kepada tiga bahagian, iaitu pengelasan piksel kulit manusia, pengekstrakkan kawasan kulit dan juga pengesan mulut dalam pengekstrakkan kawasan kulit. Gaussian mixture model (GMM), Bayesian model, dan Multi Layer Perceptrons (MLP) adalah tiga kaedah yang diketahui untuk pengelasan kulit. GMM dipilih berdasarkan keperluan memori yang sedikit berbanding dengan kaedah Bayesian dan kos pengkomputeran yang rendah berbanding dengan kaedah MLP. Eksperimen telah menunjukkan pengelasan kulit manusia yang tepat amat diperlukan untuk menghasilkan keputusan yang baik pada pengesan mulut dalam pengelasan kawasan kulit.

Penglabelan sambungan komponen adalah satu algoritma pengekstrakkan kawasan yang selalu digunakan dan disediakan dalam kesemua set perisian pemprosesan imej digunakan untuk pengekstrakkan kawasan kulit yang telah dibentuk oleh pengelasan piksel kulit. Dengan menggunakan pengekstrakkan kawasan, dalam kawasan terdapat

tujuh rongga (dua rongga untuk alis mata, dua rongga untuk mata, dua rongga untuk lubang hitung, satu rongga untuk mulut) dikesan sebagai “muka dan mulut dikesan” kawasan yang hanya terdapat dua rongga akan dikesan sebagai “muka dengan mulut tidak dapat dikesan” dan isyarat akan dihantar kepada sistem untuk menghalang audio masukan secara berterusan, ini membolehkan bunyi batuk dituhankan secara automatik. Sistem akan menghantar isyarat ke audio masukan untuk mebenarkan audio masukan semula apabila mengesan “muka dan mulut dikesan”.

Dengan menggunakan tiga komponen yang telah dikenalpasti, satu prototaip perisian telah direka dan dibagunkan. Keputusan menunjukkan pelaksanaan sistem hanya boleh mengesan “muka dan mulut dikesan” dan “muka dengan mulut tidak dapat dikesan” dalam keadaan unggul dengan tahap kelajuan 5 bingkai imej sesaat.

CHAPTER I

INTRODUCTION

1.1 Introduction Project

Coughing is a common action that appears in our daily life. Normally, human did not care so much about coughing, but the noise produced by coughing in a video conferencing will be amplified and disturb the participants of the conference. Coughing is a sudden and often repeatedly occurring reflex action started by stimulation of sensory nerves in the lining of the respiratory passage and there is a short intake of breath and the larynx. This unpleasant sound come from coughing will make human feel unconvincing where human's ear did not suitable to hear this kind of noise and the ear will lose their ability to hear if keep exposed to this noise for a long period.

Coughing produced unpleasant sound while communicating through video conferencing and human being tend to cover their mouth with hand to reduce the volume of the produced unpleasant sound. Making use of both the common reaction produced by the human being and the camera used during the video conferencing, it is possible to process the image frames captured by the camera to detect the coughing and mute the input audio automatically.

When a user covers his mouth with hand to reduce the volume of noise generated by coughing, his mouth will be blocked by the hand and hence cannot be seen in the

image captured by the camera. An image is formed by a two dimensional array of pixel elements. The type of values stored in the pixels will be different depend on the type of images produced by the camera. The type of value stored in each of the pixels of a color image will be the color information representing the captured information. A lip with red color will produce a region of pixels (depend on the distance of the lip to the camera, the nearer the lip to the camera, the larger is the region) with red pixel values in the captured image. A simple thresholding algorithm can be applied to detect the present of mouth (region of red pixels) in the captured image. However, object with similar color within the view point of the camera will be falsely detected as mouth too.

1.2 Problem Statement

To prevent the coughing sound to be heard by other people at other side through the video conferencing, the input audio is suppressed while one of them is coughing. An image processing approach is employed to detect the action of coughing (covering the mouth with hand) and give a signal to the video conferencing system to suppress the input audio.

A simple color thresholding method fails to detect the present of lips if object with similar color is around the view point of the camera. Since the mouth is located within the face region, the spatial information shall be made used to detect the present of mouth.

The process of detecting the face region required firstly classified each of the image pixels as “skin” or “non-skin” and subsequently groups all the nearby similar pixels into regions. Color space is used for skin classification where the human’s skin pixels are in color. A lot of color spaces are widely use in image processing. RGB and HSV are well known color space. Due to the time constraint, the RGB color space is used in this project.

Thresholding is a simple method that can be used for the skin classification. Using a valid skin sample, every pixels of an image can be decided easily as skin pixel or non-skin pixel. However, with the growing of the number of skin sample, the process
