ACKNOWLEDGEMENT

I would like to express a warm gratitude to everyone who involved directly or indirectly during accomplishment this report. Heartfelt thankfulness goes to Mdm. Fatimah Az-Zahrah bt Mohd Sa'at for guiding in order to complete this report. Because of her guiding I have accomplish this report from beginning and complete promptly. Also, I would like to thankful to personnel who lecturer from Department of Mechanical Engineering because have continuously, encouraging and guiding me and also gave me supports and advices.

Deepest appreciation goes to my parents and all of my family members. Besides, I would like to thank my entire friend that had give support and help. Finally I would like to thankful to all individual that have involve direct or indirectly to accomplish this report. Thank you.

ABSTRACT

This study presents a set of parametric study on heat exchanger which specifically to automotive radiator. Numerical simulation was done in this study to investigate the influences of parameter to the radiator. Heat transfer performance prediction has been done using CFD codes. Three-dimensional simulation of flat tube and fin has been conducted. Simulation has been performed with different value of air inlet temperature, air and coolant mass flow. The experimental data bank had been used to verify and validate this numerical data. In this study, CFD calculation has been compared to previous published paper. The results have show the utility of this numerical simulation model as a rating and design tool for radiator manufacturers.

ABSTRAK

Kajian ini menampilkan satu set kajian parameter terhadap penukar haba yang menjurus kepada radiator automotif. Simulasi berangka telah digunakan dalam kajian ini untuk mengkaji pengaruh parameter terhadap radiator. Ramalan prestasi pemindahan haba menggunakan kod CFD. Simulasi tiga-dimensi tiub leper dan sirip telah dilaksanakan. Simulasi telah dijalankan pada nilai yang berbeza dengan kepelbagaian suhu udara masukan, jisim aliran air dan udara. Simulasi berangka ini telah menggunakan data daripada eksperimen untuk pengesahan data. Dalam kajian ini, pengiraan menggunakan CFD telah dibandingkan dengan jurnal kajian yang sebelumnya. Keputusan kajian ini akan menunjukkan kegunaan model simulasi berangka sebagai perkadaran dan bahan rekaan untuk pengilang radiator.

CHAPTER 1

Introduction

1.1 Background

A heat exchanger is a specialized device that assists in the transfer of heat from one fluid to the other. When a fluid is used to transfer heat, the fluid could be a liquid, such as water or oil, or could be moving air. This heat will transfer through the metal surface, while convection is used to transfer heat through the liquid. In some cases, a solid wall may separate the fluids and prevent them from mixing. In other designs, the fluids may be in direct contact with each other. In the most efficient heat exchangers, the surface area of the wall between the fluids is maximized while at once minimizing the fluid flow resistance. Fins or corrugations are sometimes used with the wall in order to increase the surface area and to induce turbulence.

There are various types of heat exchangers which are air-to-liquid cooling, liquid-to-air cooling, liquid-to-liquid cooling, or air-to-air cooling. With air-to-liquid cooling, heat is transferred from the air to a liquid. One example of air-to-liquid cooling is cabinet cooling. With liquid-to-air cooling, the heat is transferred from the liquid to the air. This type of cooling is generally used to cool process fluids. Liquid-to-liquid cooling is also used to cool process fluids, but the heat is removed by another liquid instead of by air. Lastly, with air-to-air cooling, heat is transferred from one air or gas stream to another.

For [oil cooler flat tube heat exchangers](#) have tubes and fin; however, the tubes are flat instead of round. This helps to minimize [pressure drop](#) when oil or ethylene glycol is used as the coolant. The surface area of the flat tubes is also much greater than the surface area of the tubes in a tube and fin heat exchanger. The additional surface area of the tubes in an oil cooler flat tube heat exchanger maximizes heat transfer when poor heat transfer fluids like oil or ethylene glycol are used. These oil cooler heat exchangers consist of fin, flat tubes, a welded header with inlets and outlets, and plates, including an optional fan plate.

Another type of heat exchanger is a [plate-fin heat exchanger](#), which can provide air-to-air, air-to-liquid, liquid-to-air, or liquid-to-liquid cooling. Plate-fin heat exchangers consist of finned chambers separated by flat plates and are circuited in alternating hot and cold fluid passages. Heat is transferred via fins in the passageways, through the separator plate, and into the cold fluid via the separator plate, and into the cold fluid via fin once again. The heat exchanger also has manifold ducting, mounting brackets, and a frame. [Liquid-to-liquid brazed plate heat exchangers](#) also have plates, but with a herringbone pattern of grooves, stacked in alternating directions. This forms separate flow channels for two liquid streams so that the two fluids are never in direct contact. The heat exchanger plates are brazed together at the edges and at a matrix of contact points between sheets. The liquid-to-liquid heat exchanger can be compared to a shell and tube heat exchanger, which is used in similar applications.

The thermal performance of heat exchanger technologies can vary quite a bit, so when [selecting a heat exchanger](#) it's important to understand what performance is needed as well as what fluids are available for removal of heat. It's also important to evaluate the entire system when deciding on a heat exchanger, as there are a number of considerations including flow rate, pressure drop, materials compatibility, and more.

Common appliances containing a heat exchanger include air conditioners, refrigerators, and space heaters. Heat exchangers are also used in chemical processing and power production. The most well known type of heat exchanger is a car radiator, which cools the hot radiator fluid by taking advantage of airflow over the surface of the

radiator. In radiator, a solution of water and ethylene glycol, will transfer heat from the engine to the radiator and then from the radiator to the ambient air flowing through it. The solution of water and ethylene glycol known as antifreeze. This process helps to keep a car's engine from overheating. Similarly, [heat exchangers](#) are designed to remove excess heat from aircraft engines, optics, x-ray tubes, lasers, power supplies, military equipment, and many other types of equipment that require cooling beyond what air-cooled heat sinks can provide.

1.2 Problem Definition

The automotive manufacturing is endlessly involved in a well-built competitive career to attain the best automobile design in multiple aspects (performance, fuel consumption, aesthetic, safety, etc.). The air-cooled heat exchanger creates in an automotive (radiator, AC-alternative current, condenser and evaporator, charge air cooler, etc.) cover a significant function in its weight and also in the design of its front-end module, which also has a strong impact on an automobile aerodynamic behavior. For these challenges, an optimization process is compulsory to obtain the best design negotiation between performance, size/shape, and weight. The approach of this study is oriented to computationally characterize the full heat exchanger including air and liquid side influences on overall performance which are cooling capacity and pressure drop. For the case of automobile radiator, the dominant thermal resistance generally occurs on the airside which is the reduction in the air-side thermal resistance will improve the heat transfer performance of the heat exchanger. The louvered fin are expensive when the manufactured by low-speed production techniques.

1.3 Objective:

The aim of this study is to characterize the heat exchanger influences on overall performance in radiator.

1.4 Scope:

The approach of this study is oriented to computationally characterize the full heat exchanger including air and liquid side influences on overall performance which are cooling capacity and pressure drop. This study is structured in a first part where the modeling technique and formulation are briefly summarized. The numerical analysis with complex mathematical model becomes the great solution to give detailed predictions on the effects that the heat transfer enhancing techniques and design which can have on the devices performance.

This study is limited:

- i) To identify parameter that influences heat exchanger performance. This study is focusing on the influence of working condition on both fluids which are air and coolant mass flows air inlet temperature.
- ii) To computationally simulate the effect of those parameter to heat exchanger performance. In this study, the CFX. Codes will be used.

CHAPTER 2

LITERATURE REVIEW

2.1 Introduction to Radiator

In recent years a growing and intense attention has been turned to the study of concept compact heat exchanger which is application in automotive radiator. Since it represent a good solution in terms of dimension and efficiency for industrial application compared to the traditional approach. In automotive applications the use of compact heat exchanger helps in reaching high levels of temperature and pressure within severe constraints of dimensions. Manufacturing compact heat exchanger is worth as heat can be transferred using devices of limited dimensions (Carluccio *et al.*2005). According to Dittus *et al.* (1985), heat to be dissipated from water-cooled internal combustion engines is usually transferred to the atmosphere by means of devices commonly called radiator. Radiator is a component that control engine temperature in automobile where liquid to be cooled by air. Air is a medium to transfer heat to the surrounding. In radiator, cooling is made by means of air pushed to the heat exchanger by an external fan. Cihat and Feridum-Ozguc.A (2006) found that radiator is hotter than surrounding, where heat will transfer to the air and water exits at lower temperature. It was equipped with convection fins to improve heat output which is mostly by natural convection. The contribution of radiative heat transfer to the total heat transfer is smaller than the natural convection heat transfer. As found by Olsson and Sunden (1996), the medium conveying heat to radiator is water where heat is flowing from tube to liquid and medium conveying heat away is

air. Liquid will be flown in tubes while the air flow in channel set up by fin surfaces. The thermal resistance on the air is larger than on the liquid side. Besides, the previous study by Dittus and Boelter (1985) found that heat carried from warm water to colder tube by two processes which are convection and conduction. Inside the tube, fluid flow mostly turbulent. In the region of turbulent flow, most of the heat is transferred from the liquid to the tube wall by forced convection. As a consequence of the low thermal conductivity of fluids, very little heat is transferred from the center of the stream to the tube wall by conduction. In the viscous flow region, heat will transfer from interior stream to tube wall by conduction.

In order to improve the heat transfer surfaces applied the turbulence flow (Olsson and Sunden (1996)). The fluid flow is turbulent, unless the tube diameter is very small (Dittus and Boelter (1985)). The tubes dimension length can not be used very long because temperature different between bulk of fluid and wall at outlet measure with sufficient accuracy. The inlet tubes suspended with no nearby surface and at atmospheric pressure and no effect of distortion due to low pressure in tubes. Water flowing around the tube in cross flow with speed 1m/s and two-dimensional contraction placed upstream of tube to make water flow uniform. The heat transfer coefficient at the outer tube is larger than the inside wall. For the higher velocities, the maximum heat transfer rate appears at higher radius of tube. The variations of maximum heat transfer rate and optimum dimension as a function of radiator volume fraction for three different environment temperatures. The increase of radiator volume fraction increases the maximum heat transfer rate and optimum tube diameter (Olsson and Sunden, (1996)). For this study, the flow inside the tube was assumed turbulent flow. The variations of maximum heat transfer rate and optimum tube radius as a function of radiator volume fraction for three different ambient fluid temperatures. Cihat and Feridum-Ozguc (2006) found that the maximum heat transfer rate depends on ambient temperature but the corresponding optimum tube radius does not depend on this parameter.

Figure 2.1: Radiator and fin pitch (Source: Carluccio *et al.* (2005))

In addition, for the smooth tube exhibits the lowest friction factor. All the other tubes which are rib-roughened, dimpled and offset strip fin tubes have larger friction factors, f , at both laminar and turbulent. All the enhanced tubes have better heat transfer performance than the smooth tube. The dimpled tubes show a slightly better performance than the offset strip fin tube, while the smooth tube takes the lowest position. For the offset strip fin tubes, boundary layers are developed periodically I-short channel formed by the fins (Olsson and Sunden (1996)).

The rate heat from water to its air retarded by resistance on water side of tube surface, thermal resistance and resistance on air side of tube (Dittus and Boelter (1985)). Besides, the thermal resistance outside the tubes is less than the inside of tube so assume it negligible. The thermal resistance on the air is larger than on the liquid side. Flat tubes on liquid have small dimension to enhance heat transfer processes. For higher effectiveness the tubes made of brass and the fin made of aluminum (Olsson and Sunden

(1996)). Besides, the study by Malapure *et al.* (2007) found that the temperature of the fin decreases with the distance from the tube surface because of the thermal resistance of fin and carried away by the cooling air. Analysis by Dittus and Boelter (1985) on heat transfer in tubular radiator indicates that a large part of the total resistance to heat flow because the relatively low film transfer factors on the air side of the tubes. So that, any attempt to increase the overall heat transfer factor in radiator should begin by improving the film transfer factor on the air side of the tube. Some improvements might be also made by decreasing the film resistance on the liquid side of the tubes, although the total gain will be slight unless the air film transfer factor increases materially at the same time.

Figure 2.2: Flat-sided tube and louvered plate fin heat exchanger
(Source: Malapure *et al.* (2007))

While, the tube length influence on the Nusselt number, Nu is more pronounced in laminar flow than in turbulent flow. The difference in performance between the enhanced tubes will be decreased (Olsson and Sunden (1996)). Besides, the decreasing values of Nusselt number, Nu , with the distance from the entrance together with the decrease of the temperature difference between wall and air. The Nusselt number, Nu , with reference to the flow direction will be decreased of local heat transfer convective coefficient, h , going from the entrance to the exit and makes possible to understand the heat transfer coefficient behaviour at the direction changes (Carluccio *et.al.* (2005)).
